

## AS3834

### 4 channel high-precision LED controller for 3D-LCD backlight with integrated step-up controller

#### 1 General Description

The AS3834 is a 4 channel high precision LED controller with PWM inputs for driving external bipolar transistors in LCD-backlight panels, optimized for 2D and 3D operation.

The integrated step-up controller provides the necessary output voltage for the LED string supply.

The SMPS feedback control optimizes the power efficiency by adjusting the LED string supply voltage.

Build in safety features include under-voltage and thermal shutdown as well as open and short LED detection.

- Output current up to 270mA per channel
- Absolute current accuracy  $\pm 0.8\%$
- Channel to channel accuracy  $\pm 0.6\%$
- 4 separated PWM inputs
- Open LED detection and disconnect
- Short LED protection and auto-turnoff
- Undervoltage shutdown
- Temperature shutdown
- Temperature supervision of external BJT
- BJT Beta compensation
- SMPS feedback control
- DCDC Softstart Function
- Over Voltage Protection (OVP)
- Package SOIC-28, TQPF-32
- Package

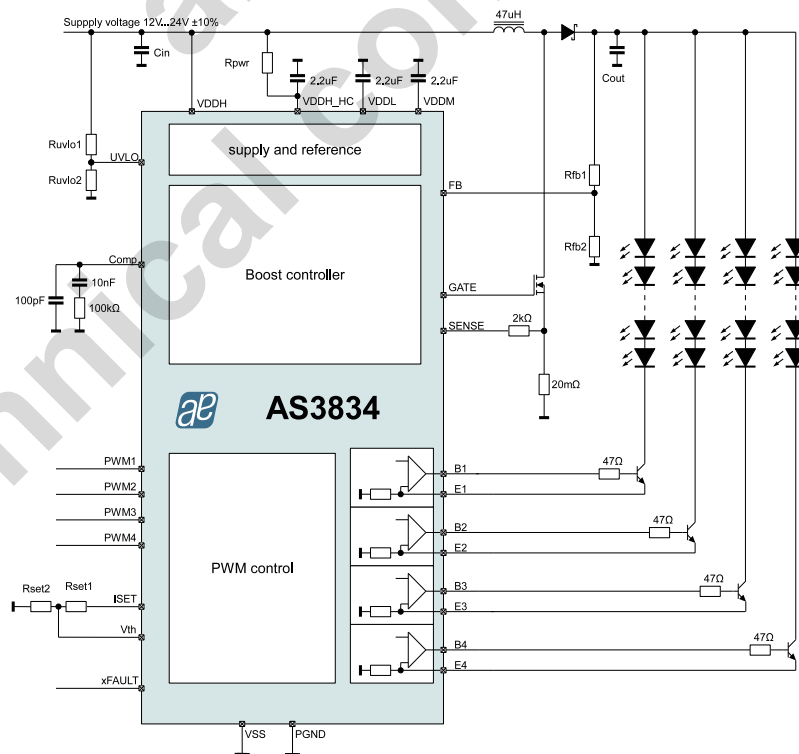

#### 2 Key Features

- 4 channel LED controller
- Step-up controller optimized for 2D/3D mode
- Supply voltage range: 12V to 50V

#### 3 Applications

LED backlighting for 3D-LCD backlight TV sets and monitors

Figure 1. AS3834

## 5 Absolute Maximum Ratings

Stresses beyond those listed in [Table 2](#) may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in [Electrical Characteristics on page 6](#) is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 2. Absolute Maximum Ratings

Parameter	Min	Max	Units	Comments
<b>Electrical Parameters</b>				
VDDH to VSS, VDDH_HC to VSS	-0.3	55	V	
VDDM to VSS, GATE to VSS	-0.3	25	V	
xFAULT to VSS	-0.3	7	V	
VDDL to VSS	-0.3	5	V	
Analog Pin Voltage to VSS <sup>1</sup>	-0.3	5	V	
Digital Pin Voltage to VSS <sup>2</sup>	-0.3	5	V	
Input Current (latch-up immunity)	-100	100	mA	Norm: JEDEC 78
<b>Electrostatic Discharge</b>				
Electrostatic Discharge HBM		+/- 1500	V	Norm: MIL 883 E method 3015
Electrostatic Discharge MM		+/- 200	V	Norm: JESD22-A115C
<b>Continuous Power Dissipation (TA = +70°C)</b>				
Continuous Power Dissipation		1.5	W	PT <sup>3</sup> for SOIC-28 Package
Continuous Power Dissipation Derating Factor		13	mW / °C	PDERATE <sup>4</sup>
<b>Temperature Ranges and Storage Conditions</b>				
Junction to ambient thermal resistance		76	°C/W	SOIC-28 Package. For more information about thermal metrics, see application note AN01 Thermal Characteristics.
Junction Temperature (T <sub>Jmax</sub> )		+150	°C	
Storage Temperature Range	-55	+150	°C	
Package Body Temperature		+260	°C	The reflow peak soldering temperature (body temperature) specified is in accordance with IPC/JEDEC J-STD-020 "Moisture/Reflow Sensitivity Classification for Non-Hermetic Solid State Surface Mount Devices". The lead finish for Pb-free leaded packages is matte tin (100% Sn).
Humidity non-condensing	5	85	%	
Moisture Sensitive Level	1			Represents a max. floor life time of unlimited

1. Pins Vth, UVLO, Comp, Sense, FB, Iset, Ex, Bx

2. Pins PWMx

3. Depending on actual PCB layout and PCB used.

4. PDERATE derating factor changes the total continuous power dissipation (PT) if the ambient temperature is not 25°C. Therefore for e.g. TA=85°C calculate PT at 85°C = PT - PDERATE x (85°C - 25°C)

## 6 Electrical Characteristics

VDDH = 24V, all voltages referenced to VSS, Typical values are at TA = +25°C (unless otherwise specified). All limits are guaranteed. The parameters with min. and max values are guaranteed with production tests or SQC (Statistical Quality Control) methods.

Table 3. Electrical Characteristics

Symbol	Parameter	Conditions	Min	Typ	Max	Units
<b>General</b>						
TA	Operating Temperature Range	apply proper cooling to stay below maximum allowed TJ.	-20		+85	°C
TJ	Operating Junction Temperature		-20		+115	°C
<b>Power supply</b>						
VDDH	Supply Voltage		+12		+50	V
VDDM	Driver supply voltage regulator output			+9		V
VDDL	3V voltage regulator output			+3.3		V
IDD	Operating Current Consumption	UVLO=2V, PWM1=0, Rset=6kΩ, Vth=0.47V	3.7	4.3	4.8	mA
IDDQ	Quiescent Current Consumption	UVLO=0V, PWM1=0, Rset=6kΩ, Vth=0.47V	2.25	2.50	2.75	mA
<b>Current sink parameters</b>						
I <sub>LED_100</sub>	Trimmed current accuracy	I <sub>LED</sub> =100mA, Tj = 25°C excluding error of Rset	-0.8		+0.8	%

Figure 5.  $V_{OUT}$  vs.  $I_{OUT}$ ,  $V_{IN} = 13V$

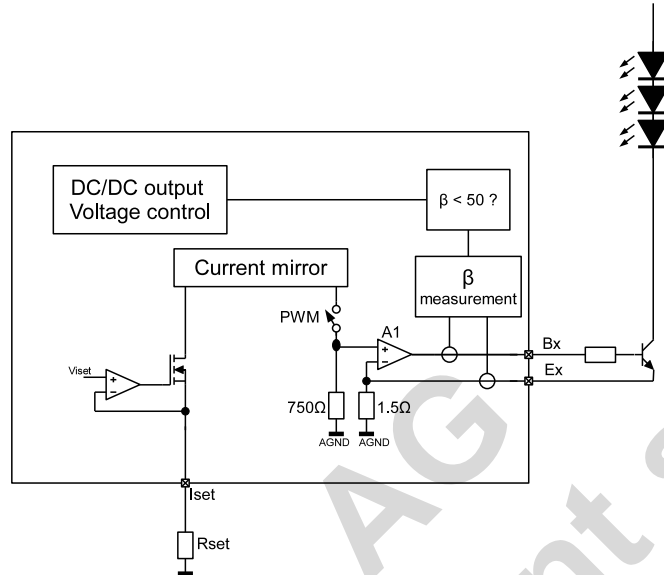

Figure 6.  $V_{OUT}$  vs.  $I_{OUT}$ ,  $V_{IN} = 24V$ Figure 7. Boost - Efficiency vs. Input Voltage,  $I_{OUT} = 1A$ Figure 8.  $V_{OUT}$  vs. Temp,  $V_{IN} = 24V$ ,  $I_{OUT} = 0.2A$ 

## 8 Detailed Description

### 8.1 Precision current output

Figure 9. Current output stage

The LED-current is derived from either Rset using the following equation

$$I_{LED} = \text{RATIO} \times I_{set} = \text{RATIO} \times \frac{V_{set}}{R_{set}} = 500 \times \frac{1.2V}{R_{SET}} \quad (\text{EQ 1})$$

$I_{set}$  is protected against a short to ground. In the case of a ground short the current  $I_{set}$  is limited to 660uA and the LED-current to 330mA.

$I_{set}$  has a lower limit of 6uA with a 1uA hysteresis. This sets the lower limit of the LED-current to 3mA with  $R_{set}=200k\Omega$ . If  $R_{set}$  is large than 200kΩ, the LED-current is set to 0mA.

## 8.2 VDDH\_HC resistor

Figure 10. VDDH\_HC resistor

Pin VDDH\_HC is connected to an internal 3.3V voltage regulator. In order to keep the power dissipation of this regulator low, it is recommended to connect pin VDDH\_HC to the power supply  $V_{in}$  with a resistor. The resistor should guarantee sufficient voltage drop so that the remaining voltage at pin VDDH\_HC is approximately 5V. The power dissipation of the  $R_{VDDH\_HC}$  has to be considered.

$$R_{VDDH\_HC} = \frac{V_{in} - 5V}{50mA} \quad (EQ 2)$$

$$P_{R_{VDDH\_HC}} = (50mA)^2 \times R_{VDDH\_HC} \quad (EQ 3)$$

Typical values for  $R_{VDDH\_HC}$  are:

$V_{IN} = 13V$ :  $R_{VDDH\_HC} = 150\Omega / 0.5W$

$V_{IN} = 24V$ :  $R_{VDDH\_HC} = 380\Omega / 1.5W$

## 8.3 Safety features

### 8.3.1 Undervoltage lockout

In order to avoid startup of the Boost controller at low supply voltage an undervoltage lockout function is implemented. The boost controller only turns on when the voltage at pin UVLO exceeds  $V_{UVLO}$ . Once the boost controller is turned on a current source  $I_{UVLO\_Hyst}$  is activated which increases the UVLO voltage and so shifts the turn off voltage level.

Figure 11. Undervoltage lockout

Following equations can be derived for adjusting the threshold voltages:

$$\text{Undervoltage lockout HIGH level: } V_{DDH\_UVH} = V_{UVLO} \times \left(1 + \frac{R_{UVLO1}}{R_{UVLO2}}\right) \quad (\text{EQ 4})$$

$$\text{Undervoltage lockout LOW level: } V_{DDH\_UVL} = V_{UVLO} \times \left(1 + \frac{R_{UVLO1}}{R_{UVLO2}}\right) - I_{UVLO} \times R_{UVLO1} \quad (\text{EQ 5})$$

### 8.3.2 Overtemperature Shutdown

If the device temperature reaches  $T_{OFF}$  the boost controller and all current outputs are turned off. After the temperature has decreased by  $T_{hyst}$  all blocks are turned on again.

### 8.3.3 Short LED protection

Figure 12. Short Led protection

A built in short protection comparator is monitoring the junction temperature  $T_J$  of the external bipolar transistors by measuring the base-emitter voltage  $V_{BE}$ .

$$V_{BE} = 1,2V - 0.002 \times T_J \quad T_J \dots \text{junction temperature in K} \quad (\text{EQ 6})$$

When the measured  $V_{BE}$  gets lower than the voltage applied at pin  $V_{th}$  an overtemperature and hence an short LED condition is detected. Subsequently the fault output is activated ( $xFAULT = 0$ ) and the corresponding output is deactivated.

### 8.3.4 Open LED detection

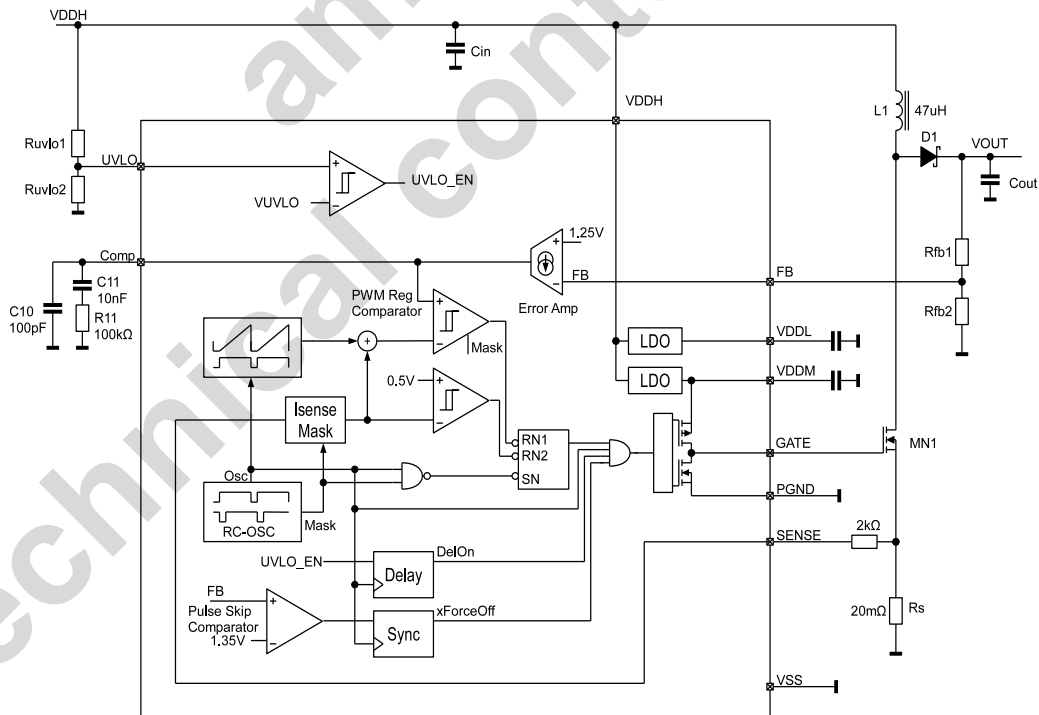

Figure 13. Open Led detection

A broken LED-string is detected during PWM=1. If a LED-string is broken the power supply feedback will increment the IDAC to increase the power supply output voltage. After the IDAC has reached its maximum value, a debounce counter is started. In order to run the debounce counter, the corresponding PWM-signal has to be high for more than 150 $\mu$ s. After the debounce counter has counted up for 32ms, the fault output is activated (xFAULT = 0) and the corresponding output is disconnected from the power supply feedback loop.

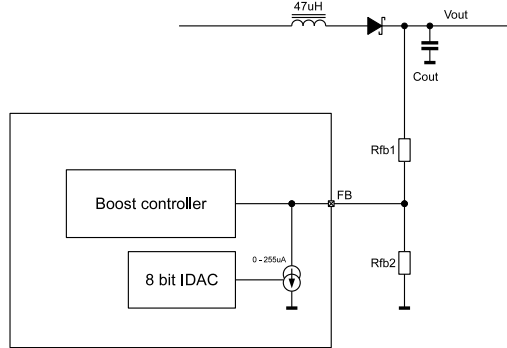

### 8.4 Boost controller

Figure 14. Boost controller

### 8.4.1 Setting the output voltage

Figure 15. Vout setting

According to the requirements of the LED strings, the output voltage Vout is adjusted by the internal power supply feedback

$$\text{between: } V_{OUTmin} = V_{fb} \left( 1 + \frac{R_{fb1}}{R_{fb2}} \right) \quad \text{and} \quad V_{OUTmax} = V_{fb} \left( 1 + \frac{R_{fb1}}{R_{fb2}} \right) + 255\mu A \cdot R_{fb1}$$

Once Vout\_min and Vout\_max is known the external resistors can be calculated:

$$R_{fb1} = \frac{(V_{OUTmax} - V_{OUTmin})}{255\mu A} \quad (EQ 7)$$

$$R_{fb2} = \frac{V_{fb} R_{fb1}}{(V_{OUTmin} - V_{fb})} \quad (EQ 8)$$

**Note:** The overall resistance should be in the range of 100kΩ to 200kΩ to avoid any noise issues. Keep FB-line as short as possible.

### 8.4.2 Continuous Conduction Mode (CCM)

For normal operation the converter should stay in continuous conduction mode, to ensure that the inductor value must be bigger than  $L_{CRIT}$ .

$$L_{CRIT} = \frac{\left(1 - \frac{V_{IN}}{V_{OUT} + V_D}\right) \times V_{IN}^2 \times R}{2 \times f_{SW} \times (V_{OUT} + V_D)^2} \quad (EQ 9)$$

#### Where:

$V_{IN}$  ... Input voltage at VDDH

$V_{OUT}$  ... Output voltage

$V_D$  ... Diode forward voltage at D1

$f_{SW}$  ... Switching frequency

$R$  ... Load resistor, should be calculated with minimum current load  $R = V_{OUT} / I_{OUT\_min}$

$I_{OUT\_min}$  ... Minimum output current (e.g. for LED driver only one LED string is on)

### 8.4.3 Duty Cycle

Within CCM, the well known relation between input and output voltage is deripied in the following equation:

$$\frac{V_{OUT} + V_D}{V_{IN}} = \frac{1}{1 - D} \quad (EQ 10)$$

this means for the duty cycle:

$$D = 1 - \frac{V_{IN}}{V_{OUT} + V_D} \quad (EQ 11)$$

### 8.4.4 Inductor Current

The inductor current varies during a switching cycle. This variation can be expressed by the mean value of the inductor current and the delta rise/fall current within each cycle (see Figure 16).

Figure 16. Inductor Current

Mean inductor current:

$$\bar{I}_L = \frac{I_{OUT}}{1 - D} \quad (EQ 12)$$

Delta inductor current:

$$\Delta I_L = \frac{D \times V_{IN}}{f_S \times L} \quad (EQ 13)$$

Peak current:

$$I_{pk} = \bar{I}_L + \frac{\Delta I_L}{2} = \frac{I_{OUT}}{1-D} + \frac{D \times V_{IN}}{2 \times f_S \times L} \quad (EQ 14)$$

RMS inductor current:

$$I_{RMS} = \sqrt{\bar{I}_L^2 + \left(\frac{1}{12} \times \Delta I_L\right)^2} \quad (EQ 15)$$

This peak current is flowing through MN1 during phase 1 and through D1 during phase 2 of each cycle. Therefore this peak current is important for a proper diode, MOSFET and inductor selection.

**Note:** The saturation current of the inductor should be about 20 to 30% larger than the peak current

#### 8.4.5 Input Capacitor

The input capacitor has to supply the delta inductor current and it should be selected according to:

$$C_{IN} > \frac{\Delta I_L}{4 \times \Delta V_{IN} \times f_{SW}} \quad (EQ 16)$$

$$ESR < \frac{\Delta V_{IN}}{2 \times \Delta I_L} \quad (EQ 17)$$

#### 8.4.6 Output Capacitor

The output capacitor must be chosen according to the max allowable output ripple at high load.

$$C_{OUT} > \frac{I_{OUT-max} \times D}{\Delta V_{OUT} \times f_{SW}} \quad (EQ 18)$$

$$ESR < \frac{\Delta V_{OUT}}{\left(\frac{I_{OUT}}{1-D} + \frac{V_{IN} \times D}{2 \times L \times f_{SW}}\right)} \quad (EQ 19)$$

#### 8.4.7 Current Sense Resistor

$$R_{S-max} = \frac{V_{SENSE}}{\bar{I}_L + 0,5 \times \Delta I_L} \quad (EQ 20)$$

$$P_{RS} = I_{L-rms}^2 \times R_S \times D \quad (EQ 21)$$

**Note:** Low inductance, specific designed current sensing resistors should be used, e.g. Stackpole Electronics CSR/CSRN series of sensing resistors with less than 0.2nH (typ.).

#### 8.4.8 Compensation Network

A typical choice for values of the compensation network is C10 = 100pF, C11 = 10nF, R11 = 100KΩ. Use these values as initial choice and evaluate the transient response of the system to verify the behavior at output load change.
