

AS5047D

14-bit On-Axis Magnetic Rotary Position Sensor with 11-bit Decimal & **Binary Incremental Pulse Count**

General Description

The AS5047D is a high-resolution rotary position sensor for fast absolute angle measurement over a full 360-degree range. This new position sensor is equipped with revolutionary integrated dynamic angle error compensation (DAEC™) with almost 0 latency and offers a robust design that suppresses the influence of any homogenous external stray magnetic field.

A standard 4-wire SPI serial interface allows a host microcontroller to read 14-bit absolute angle position data from the AS5047D and to program non-volatile settings without a dedicated programmer.

Incremental movements are indicated on a set of ABI signals with a maximum resolution of 2000 steps / 500 pulses per revolution in decimal mode and 2048 steps / 512 pules per revolution in binary mode. The resolution of the ABI signal is programmable and can be reduced to 32 steps per revolution, or 8 pulses per revolution.

Brushless DC (BLDC) motors are controlled through a standard UVW commutation interface with a programmable number of pole pairs from 1 to 7. The absolute angle position is also provided as PWM-encoded output signal.

The AS5047D is available as a single die in a compact 14-pin TSSOP package.

Ordering Information and Content Guide appear at end of datasheet.

Key Benefits & Features

The benefits and features of AS5047D, 14-bit On-Axis Magnetic Rotary Position Sensor with 11-bit Decimal & Binary Incremental Pulse Count are listed below:

Figure 1: Added Value of Using the AS5047D

| Benefits | Features |
|--|--|
| Easy to use – saving costs on DSP | • DAEC™ Dynamic angle error compensation |
| Good resolution for motor & position control | • 14-bit core resolution |
| Simple optical encoder replacement | ABI programmable decimal and binary pulse-count: 500, 400, 300, 200, 100, 50, 25, 8, 512, 256 ppr |
| No programmer needed (via SPI command) | Zero position, configuration programmable |

| Benefits | Features |
|-----------------------------------|---|
| Versatile choice of the interface | Independent output interfaces: SPI, ABI, UVW, PWM |
| Lower system costs (no shielding) | Immune to external stray field |

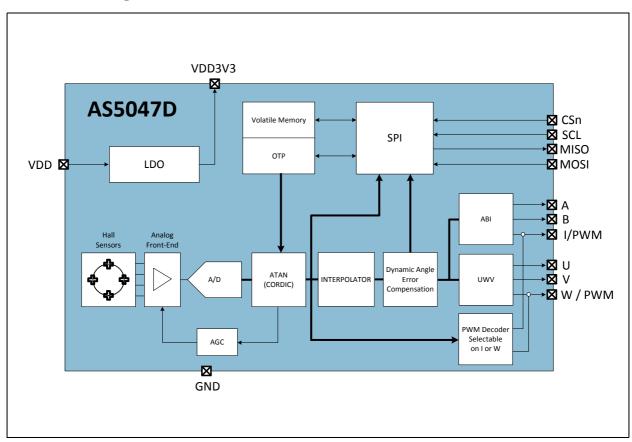

Applications

The AS5047D is ideally suited to support BLDC motor commutation for the most challenging industrial applications such as factory automation, building automation, robotics, PMSM (permanent magnet synchronous motor) and stepper motors closed loop regulation, as well as optical encoder replacement.

Block Diagram

The functional blocks of this device are shown below:

Document Feedback

| Pin Number | Pin Name | Pin Type | Description |
|------------|----------|---------------------|--|
| 8 | W/PWM | Digital output | Commutation signal W or PWM |
| 9 | V | Digital output | Commutation signal V |
| 10 | U | Digital output | Commutation signal U |
| 11 | VDD | Power supply | 5V power supply voltage for on-chip regulator |
| 12 | VDD3V3 | Power supply | 3.3V on-chip low-dropout (LDO) output. Requires an external decoupling capacitor (1 μ F) |
| 13 | GND | Power supply Ground | |
| 14 | ı | Digital output | Incremental signal I (index) or PWM |

Note(s):

- 1. Floating state of a digital input is not allowed.
- 2. If SPI is not used, a Pull up resistor on CSn is required.
- 3. If SPI is not used, a Pull down resistor on CLK and MOSI is required.
- 4. If SPI is not used, the pin MISO can be left open.
- 5. If ABI, UVW or PWM is not used, the pins can be left open.

Detailed Description

The AS5047D is a Hall-effect magnetic sensor using a CMOS lateral technology. The lateral Hall sensors convert the magnetic field component perpendicular to the surface of the chip into a voltage.

The signals from the Hall sensors are amplified and filtered by the analog front-end (AFE) before being converted by the analog-to-digital converter (ADC). The output of the ADC is processed by the hardwired CORDIC (coordinate rotating digital computer) block to compute the angle and magnitude of the magnetic vector. The intensity of the magnetic field (magnitude) is used by the automatic gain control (AGC) to adjust the amplification level for compensation of the temperature and magnetic field variations.

The internal 14-bit resolution is available by readout register via the SPI interface. The resolution on the ABI output can be programmed from 2048 to 32 steps per revolution.

The Dynamic Angle Error Compensation block corrects the calculated angle regarding latency, by using a linear prediction calculation algorithm. At constant rotation speed the latency time is internally compensated by the AS5047D, reducing the dynamic angle error at the SPI, ABI and UVW outputs. The AS5047D allows to switch OFF the UVW output interface to display the absolute angle as PWM-encoded signal on the pin W.

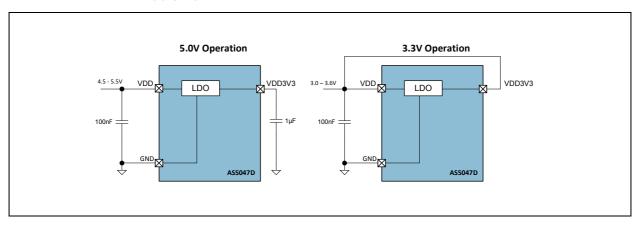

At higher speeds, the interpolator fills in missing ABI pulses and generates the UVW signals with no loss of resolution. The non-volatile settings in the AS5047D can be programmed through the SPI interface without any dedicated programmer.

Power Management

The AS5047D can be either powered from a 5.0V supply using the on-chip low-dropout regulator or from a 3.3V voltage supply. The LDO regulator is not intended to power any other loads, and it needs a 1 μ F capacitor to ground located close to the chip for decoupling as shown in Figure 10.

In 3.3V operation, VDD and VREG must be tied together.

Figure 10: 5.0V and 3.3V Power Supply Options

ams Datasheet
[v1-06] 2016-Jan-28
Document Feedback

After applying power to the chip, the power-on time (t_{pon}) must elapse before the AS5047D provides the first valid data.

Dynamic Angle Error Compensation

The AS5047D uses 4 integrated Hall sensors which produce a voltage proportional to the orthogonal component of the magnetic field to the die. These voltage signals are amplified, filtered, and converted into the digital domain to allow the CORDIC digital block to calculate the angle of the magnetic vector. The propagation of these signals through the analog front-end and digital back-end generates a fixed delay between the time of measurement and the availability of the measured angle at the outputs. This latency generates a dynamic angle error represented by the product of the angular speed (ω) and the system propagation delay (t_{delay}) :

 $DAE = \omega \times t_{delay}$

The dynamic angle compensation block calculates the current magnet rotation speed (ω) and multiplies it with the system propagation delay (t_{delay}) to determine the correction angle to reduce this error. At constant speed, the residual system propagation delay is t_{delay_DAEC} .

The angle represented on the PWM interface is not compensated by the Dynamic Angle Error Compensation algorithm. It is also possible to disable the Dynamic Angle Error Compensation with the setting DAECDIS. Disabling the Dynamic Angle Error Compensation gives a noise benefit of 0.016 degree rms. This setting can be advantageous for low speed (under 100rpm) respectively static positioning applications.

SPI Interface (slave)

The SPI interface is used by a host microcontroller (master) to read or write the volatile memory as well as to program the non-volatile OTP registers. The AS5047D SPI only supports slave operation mode. It communicates at clock rates up to 10 MHz.

The AS5047D SPI uses mode=1 (CPOL=0, CPHA=1) to exchange data. As shown in Figure 11, a data transfer starts with the falling edge of CSn (SCL is low). The AS5047D samples MOSI data on the falling edge of SCL. SPI commands are executed at the end of the frame (rising edge of CSn). The bit order is MSB first. Data is protected by parity.

Page 10

Document Feedback [v1-06] 2016-Jan-28

SPI Timing

The AS5047D SPI timing is shown in Figure 11.

Figure 11: SPI Timing Diagram

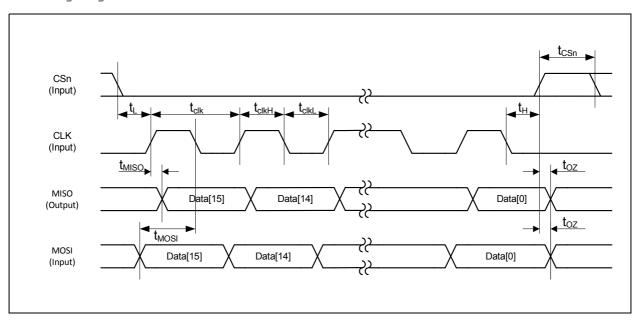

Figure 12: SPI Timing

| Parameter | Description | Min | Max | Units |
|-------------------|--|----------|-----|-------|
| t _L | Time between CSn falling edge and CLK rising edge | 350 | | ns |
| t _{clk} | Serial clock period | 100 | | ns |
| t _{clkL} | Low period of serial clock | 50 | | ns |
| t _{clkH} | High period of serial clock | 50 | | ns |

SPI Transaction

An SPI transaction consists of a 16-bit command frame followed by a 16-bit data frame. Figure 13 shows the structure of the command frame.

Figure 13: SPI Command Frame

| Bit | Name | Description |
|------|------|--|
| 15 | PARC | Parity bit (even) calculated on the lower 15 bits of command frame |
| 14 | R/W | 0: Write 1: Read |
| 13:0 | ADDR | Address to read or write |

To increase the reliability of communication over the SPI, an even parity bit PARC must be generated and sent. A wrong setting of the parity bit causes a parity bit error, which is shown as PARERR bit in the ERRFL register. The parity bit is calculated from the lower 15 bits of the command frame. The complete 16-bit command frame consists of a register address, read/write bit and the parity bit. Figure 14 shows the read data frame.

Figure 14: SPI Read Data Frame

| Bit | Name | Description |
|------|------|--|
| 15 | PARD | Parity bit (even) for the data frame |
| 14 | EF | 0: No command frame error occurred 1: Error occurred |
| 13:0 | DATA | Data |

The data is sent on the MISO pin. The parity bit PARD is calculated by the AS5047D of the lower 15 bits of data frame. If an error occurred in the previous SPI command frame, the EF bit is set high. The SPI read is sampled on the rising edge of CSn and the data is transmitted on MISO with the next read command, as shown in Figure 15.

Page 12

Document Feedback

[v1-06] 2016-Jan-28

Figure 15: SPI Read

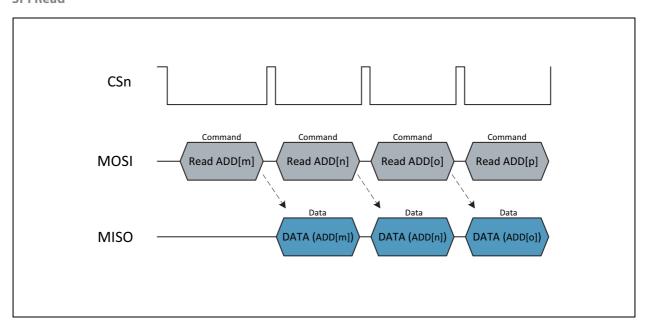

Figure 16: SPI Write Data Frame

| Bit | Name | Description |
|------|------|-------------------|
| 15 | PARD | Parity bit (even) |
| 14 | 0 | Always low |
| 13:0 | DATA | Data |

Figure 16 shows the structure of the Write Data Frame.

The parity bit PARD must be calculated from the lower 15 bit of write data frame.

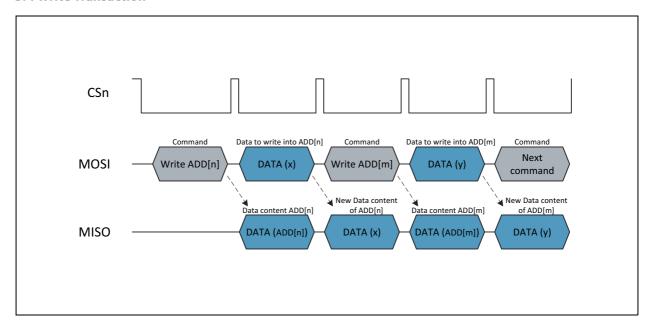

In a SPI write transaction, the write command frame is followed by a write data frame at MOSI. The write data frame consists of the new register content, which was addressed is in the previous command frame.

During data transmission on MOSI, the current register content is send on MISO. At the next command on MOSI the updated content of the register is transmitted on MISO, as shown in Figure 17.

Non-Volatile Registers (OTP)

The OTP (One-Time Programmable) memory is used to store the absolute zero position of the sensor and the customer settings permanently in the sensor IC. SPI write/read access is possible several times for all nonvolatile registers (soft write). Soft written register content will be lost after a hardware reset.

The programming itself can be done just once. Therefore the content of the nonvolatile registers is stored permanently in the sensor. The register content is still present after a hardware reset and cannot be overwritten. For a correct function of the sensor, the OTP programming is not required.

Figure 25: Non-Volatile Register Table

ABI Incremental Interface

The AS5047D can send the angle position to the host microcontroller through an incremental interface. This interface is available simultaneously with other interfaces. By default, the incremental interface is set to work at the highest resolution 2000 step per revolution, or 500 pulses per revolution (ppr). It is possible to select between a decimal and binary pulses per revolution, respectively with the bit ABIBIN and select the pulses per revolution with the bit ABIRES as shown in Figure 30.

Figure 30: ABI Resolution Setting

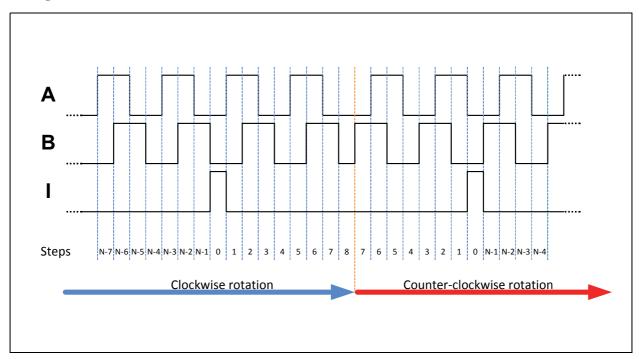

| ABIRES | ABIBIN | Steps Per Revolution | Pulses Per Revolution |
|--------|--------|----------------------|-----------------------|
| 000 | 0 | 2000 | 500 |

UVW Commutation Interface

The AS5047D can emulate the UVW signals generated by the three discrete Hall switches commonly used in BLDC motors. The UVWPP field in the SETTINGS register selects the number of pole pairs of the motor (from 1 to 7 pole pairs). The UVW signals are generated with 14-bit resolution.

During the start-up time, after power on of the chip, the UVW signals are low.

Figure 32: UVW Signals

The Figure 32 shows the UVW signal flow if the magnet rotates in clockwise direction and counter-clockwise direction (DIR=0). In this example the sensor to magnet arrangement is done like shown in Figure 43.

With the bit DIR, it is possible to invert the rotation direction.

ams Datasheet Page 21
[v1-06] 2016-Jan-28 Document Feedback

PWM

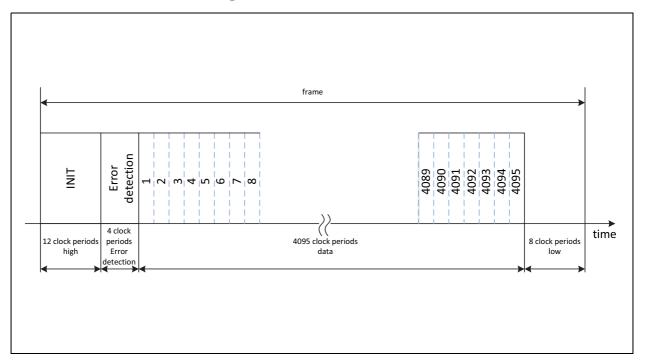

The PWM can be enabled with the bit setting PWMon. The PWM encoded signal is displayed on the pin W or the pin I. The bit setting UVW_ABI defines which output is used as PWM. The PWM output consists of a frame of 4119 PWM clock periods, as shown in Figure 33. The PWM frame has the following sections:

- 12 PWM clocks for INIT
- 4 PWM clocks for error detection
- 4095 PWM clock periods of data
- 8 PWM clock periods low

The angle is represented in the data part of the frame with a 12-bit resolution. One PWM clock period represents 0.088 degree and has a typical duration of 444 ns.

If the embedded diagnostic of the AS5047D detects any error the PWM interface displays only 12 clock periods high (0.3% duty-cycle). Respectively the 4 clocks for error detection are forced to low.

Figure 33:
Pulse Width Modulation Encoded Signal

Page 22

Document Feedback [v1-06] 2016-Jan-28

Hysteresis

The hysteresis can be programmed in the HYS bits if the SETTINGS2 register and depends on the chosen resolution of the incremental interface (ABIRES), as shown in the Figure 34.

Figure 34: Hysteresis Settings

| HYS | Hysteresis (degree) - ABIRES ≥ 1600 steps per revolution | Hysteresis (degree) - ABIRES ≤ 1024 steps per revolution |
|-----|---|---|
| 00 | 0.53 | 0.7 |
| 01 | 0.35 | 0.35 |
| 10 | 0.175 | no hysteresis |
| 11 | no hysteresis | 1.05 |

Automatic Gain Control (AGC) and CORDIC Magnitude

The AS5047D uses AGC to compensate for variations in the magnetic field strength due to changes of temperature, air gap between the chip and the magnet, and demagnetization of the magnet. The automatic gain control value can be read in the AGC field of the DIAAGC register. Within the specified input magnetic field strength (Bz), the Automatic Gain Control works in a closed loop and keeps the CORDIC magnitude value (MAG) constant. Below the minimum input magnetic field strength, the CORDIC magnitude decreases and the MAGL bit is set.

Diagnostic Features

The AS5047D supports embedded self-diagnostics.

MAGH: magnetic field strength too high, set if AGC = 0x00. This indicates the non-linearity error may be increased.

MAGL: magnetic field strength too low, set if AGC = 0xFF. This indicates the output noise of the measured angle may be increased.

COF: CORDIC overflow. This indicates the measured angle is not reliable.

LF: offset compensation completed. At power-up, an internal offset compensation procedure is started, and this bit is set when the procedure is completed.

ams Datasheet Page 23
[v1-06] 2016-Jan-28 Document Feedback

LF Error / COF Error

In case of a LF or COF error, all outputs are changing into a safe state:

SPI Output: Information in the DIAAGC (0x3FFC) register. The angle information is still valid.

PWM Output: PWM Clock Period 13 - 16 of the first 16 PWM Clock Periods = low. Additional there is no angle information valid (all 4096 clock periods = low)

ABI Output: The state of ABI is frozen to ABI = 111

UVW Output: The state of UVW is frozen to UVW = 000

MAGH Error / MAGL Error

Default diagnostic setting for MAGH error /MAGL error:

In case of a MAGH error or MAGL error, there is no safe state on the PWM, ABI or UVW outputs if comp_h_error_en= 0 and comp_l_error_en = 0.

The error flags can be read out with the DIAAGC (0x3FFC) register.

Enhanced diagnosis setting for MAGH error / MAGL error:

In case of a MAGH error or MAGL error, the PWM, ABI or UVW outputs are going into a safe state if comp_h_error_en= 1 and comp_l_error_en = 1. The device is operating with the performance as explained.

SPI Output: Information in the DIAAGC (0x3FFC) register. The angle information is still valid, if the MAGH or MAGL error flag is on.

PWM Output: PWM Clock Period 13 - 16 of the first 16 PWM Clock Periods = low. Additional there is no angle information valid (all 4096 clock periods = low)

ABI Output: The state of ABI is frozen to ABI = 111

UVW Output: The state of UVW is frozen to UVW = 000

Important: When comp_(h/l)_error_en is enabled a marginal magnetic field input can cause toggling of MAGH or MAGL which will lead to toggling of the ABI/UVW outputs between operational mode and failure mode.

Application Information

Burn and Verification of the OTP Memory

Step-by-step procedure to permanently program the non-volatile memory (OTP):

Figure 35:
Minimum Programming Diagram for the AS5047D in 5 V Operation

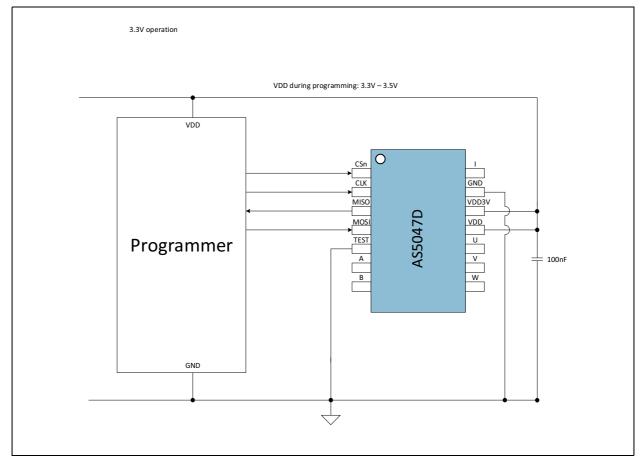

Note(s):

 $1. \ In \ terms \ of \ EMC \ and \ for \ remote \ application, \ additional \ circuits \ are \ necessary.$

ams Datasheet Page 25
[v1-06] 2016-Jan-28 Document Feedback

Figure 36: Minimum Programming Diagram for the AS5047D in 3.3V Operation

Note(s):

1. In terms of EMC and for remote application, additional circuits are necessary.

Figure 37: Programming Parameter

| Symbol | Parameter | Conditions | Min | Тур | Max | Units |
|--------------------|----------------------------|---|-----|-----|-----|-------|
| T _{aProg} | Programming temperature | Programming @ Room Temperature (25°C +-20°C | 5 | | 45 | ° |
| V _{DD} | Positive supply voltage | 5 V operation mode. Supply voltage during programming | 4.5 | 5 | 5.5 | V |
| V _{DD} | Positive supply voltage | 3.3 V operation mode. Supply voltage during programming | 3.3 | | 3.5 | V |
| I _{Prog} | Current for programming | max current during OTP burn procedure. | | | 100 | mA |

Page 26ams DatasheetDocument Feedback[v1-06] 2016-Jan-28

The programming can either be performed in 5V operation using the internal LDO ($1\mu F$ on regulator output pin), or in 3V operation but using a supply voltage between 3.3V and 3.5V.

- 1. Power on cycle
- 2. Write the SETTINGS1 and SETTINGS2 registers with the custom settings for this application (Bit0 of Settings1 is a factory bit. For programming its mandatory to set this bit to 0).
- 3. Place the magnet at the desired zero position
- 4. Read out the measured angle from the ANGLE register
- 5. Write ANGLE [5:0] into the ZPOSL register and ANGLE [13:6] into the ZPOSM register
- 6. Read reg(0x0016) to reg(0x0019) \rightarrow Read register step1
- 7. Comparison of written content (settings and angle) with content of read register step1 (Removing of Bit0 of Settings1 from the comparison is mandatory. Bit0 is preprogrammed)
- 8. If point 7 is correct, enable OTP read / write by setting PROGEN = 1 in the PROG register
- 9. Start the OTP burn procedure by setting PROGOTP = 1 in the PROG register
- 10. Read the PROG register until it reads 0x0000 (Programming procedure complete)
- 11. Clear the memory content writing 0x00 in the whole non-volatile memory
- 12. Enable OTP read / write by setting PROGEN = 1 in the PROG register
- 13. Set the PROGVER = 1 to set the guard band for the guard band test⁽¹⁾.
- 14. Refresh the non-volatile memory content with the OTP content by setting OTPREF = 1
- 15. Read reg(0x0016) to reg(0x0019) \rightarrow Read register step2
- 16. Comparison of written content (settings and angle) with content of read register step2.
 Mandatory: guard band test (Removing of Bit0 of Settings1 from the comparison is mandatory. Bit0 is preprogrammed)

ams Datasheet Page 27
[v1-06] 2016-Jan-28 Document Feedback

- 17. New power on cycle, if **point 16** is correct. If **point 16** fails, the test with the guard band test¹ was not successful and the device is incorrectly programmed. A reprogramming is not allowed!
- 18. Read reg(0x0016) to reg(0x0019) \rightarrow Read register step3
- 19. Comparision of written content (settings and angle) with content of read register step3(Removing of Bit0 of Settings1 from the comparison is mandatory. Bit0 is preprogrammed).
- 20. If **point 19** is correct, the programming was successful. If **point 19** fails, device is incorrectly programmed. A reprogramming is not allowed

Page 28

Document Feedback

[v1-06] 2016-Jan-28

^{1.} Guard band test:

⁻ Restricted to temperature range: 25 °C ± 20 °C

⁻ Right after the programming procedure (max. 1 hour with same

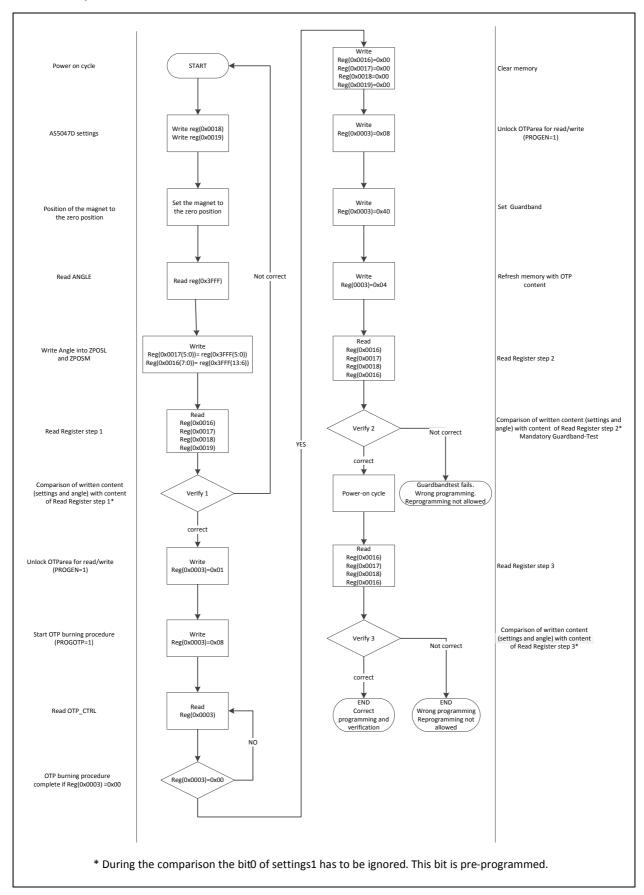

⁻ Conditions 25°C ± 20 °C)

⁻ Same VDD voltage

The guard band test is only for the verification of the burned OTP fuses during the programming sequence. A use of the guard band in other cases is not allowed.

RoHS Compliant & ams Green Statement

RoHS: The term RoHS compliant means that ams AG products fully comply with current RoHS directives. Our semiconductor products do not contain any chemicals for all 6 substance categories, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, RoHS compliant products are suitable for use in specified lead-free processes.

ams Green (RoHS compliant and no Sb/Br): ams Green defines that in addition to RoHS compliance, our products are free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material).

Important Information: The information provided in this statement represents ams AG knowledge and belief as of the date that it is provided. ams AG bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. ams AG has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. ams AG and ams AG suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.
